<div class="df_qntext">How to evaluate the performance of supercritical compressed carbon dioxide energy storage systems?

To evaluate the comprehensive performance of two proposed supercritical compressed carbon dioxide energy storage systems, thermodynamic and economic indicators will be introduced in this part. 4.1. Energy storage efficiency Since the solar energy is added, the proposed systems contain two kinds of energy: electricity and heating.

<div class="df_qntext">What is gasbag-structured supercritical carbon dioxide energy storage (G-cscs)?

Currently, feasible LSLD-ESSs, such as pumped hydro energy storage (PHES) and compressed air energy storage (CAES), face limitations due to specific terrestrial constraints. To address these challenges, gasbag-structured compressed supercritical carbon dioxide energy storage (G-CSCES) has been developed.

<div class="df_qntext">Can gasbag-structured compressed supercritical carbon dioxide energy storage be used for ancillary services?

To address these challenges, gasbag-structured compressed supercritical carbon dioxide energy storage (G-CSCES) has been developed. However, existing studies primarily focus on exergoeconomic optimization, and current cavern-structured CAES models are not applicable to G-CSCES, hindering its use for ancillary services.

<div class="df_qntext">What is compressed air energy storage (CAES)?

Compressed air energy storage (CAES) is another interesting solution. Air is compressed at the storage energy process and expanded into the Brayton cycle when energy is needed. If the air at high pressure (almost 40 bars) is heated to 470°C before the expansion, this system can reach an energy density of 0.39 MJ/kg (Giovannelli et al., 2020).
